|--------------------------------|--------------------------------|

ABSTRACT

The objective of the software system is the ability to quickly solve complex requirements and to have a more flexible architecture to apply changes faster. In general the software requirements grow more complex from time to time. Also the software should be highly configurable in no time or very less time the product should hit the software market before the competitor product reaches the market. This paper analyses the metrics of the software developed using automated multi-agent based framework prototyping a process in comparison to other engineering industry.

Keywords - Agent; Multi-Agents; Modeling Agents; Agent Oriented Software Engineering;

I. INTRODUCTION

Recent statistical study says "17 percent of large IT projects go so badly that they can threaten the very existence of the company, on average, large IT projects run 45 percent over budget and 7 percent over time, while delivering 56 percent less value than predicted [11]". These numbers suggests there are still some fundamental issues with respect to software development. After comparing with other engineering disciplines, Jack Greenfield and Keith Short [12]prescribed One-off development or development in isolation, Monolithic system increasing system complexity, working at low levels of abstraction, process immaturity and rapidly growing demand for software systems as the primary reasons for lack of predictability in software development.

Current software languages and tools work at low levels of abstraction to provide greater flexibility. Even though the third generation languages do justice by increasing the level of abstraction without compromising flexibility, still the level of abstraction is not higher enough to produce reusable code across domain and platforms. Software development processes are not matured enough in comparison with other engineering disciplines to produce flexible and predictable software. Rapidly growing demand of software increases along with the size and the complexity of the software. This brings in the necessity of standardization of software systems like other engineering divisions where two entirely different products could exchange their parts.

AGENTS BASED SOFTWARE DESIGN

Design of multi-agent based software in order to achieve

- a. Reusability of behaviors by the way of agent design
- b. Reactive, proactive, autonomous and decision making skills
- c. Dynamically configure agent behaviors, actuators, sensors and construct agents using configuration
- d. Create more modular mechanism
- e. Achieve secure communication
- f. Achieve greater separation of concern

VALIDATING AGENT BASED SOFTWARE SYSTEM

In the process of quantitative analysis, four open source software is chosen and various parameters from the code metrics were analyzed. They were named as software "A", "B", "C" and "D". Software "D" is agent based software has closer practices followed in this research. Even though software "D" did not use models and code generation but chooses technology of agent framework. In the perspective of validation the model development and code generation is outside the scope of quantitative analysis.

Using software metrics tools the data is collected for all the four software chosen to the method and class level. The abstract data looks like given in figure 1. The summary values for the software "A", "B", "C" and "D" is given in figure 2, 3, 4 and 5 respectively.

Figure 5: Summary metrics values for software "D"

The metrics and their analysis is given below in Figure 6

i) Lines of Code (Loc) - Number of lines of code available with a specific class

Lines of IL instructions (ILoc) - Number ii) of lines of code available in the intermediate language in Common Language Runtime (CLR).

Afferent coupling (Ca) – Number of types iii) outside this package that depend on types within this package.

iv) Efferent coupling (Ce) – Number of types within this package that depend on the types outside this package.

Instability (I) – ration of efferent coupling v) to total coupling

i.e. I = Ce / (Ce + Ca)

Instability = 0 indicates completely stable package, painful to modify.

Instability = 1 indicates completely instable package.

vi) Cyclomatic Complexity (CC) - The number of decisions that can be taken in a procedure, this depends on number of branching, looping statements available in the code of a particular method.

For a method CC > 15 then it would be hard to understand CC > 30 the method is extremely complex.

Figure 6: Software Metrics comparison of agent based software with other software's

II. CONCLUSION

The analysis proves the agent based software development addresses the key issues of software development by raising the level of abstraction, providing necessary modularity and providing better results for the range of software metrics. Additionally the design carried out for simulation indirectly satisfies the challenges of solving complex requirements, reducing time to market, faster implementation of change in requirement, lowering cost of production and maintenance. Overall the agent based software developments provides a step towards resolving challenges in the software industry in providing practices equivalent to other engineering disciplines.
