## ABSTRACT

We consider Z-matrices and inverse Z-matrices, i.e. those nonsingular matrices whose inverses are Z-matrices. Recently Fiedler and Markham introduced a classification of Z-matrices. This classification directly leads to a classification of inverse Z-matrices. Among all classes of Z-matrices and inverse Z-matrices, the classes of M-matrices, N0-matrices, F0-matrices, and inverse M-matrices, inverse N0-matrices and inverse F0-matrices, respectively, have been studied in detail. Here we discuss each single class of Z-matrices and inverse Z-matrices as well as considering the whole classes of Z-matrices and inverse Z-matrices.

## CHARACTERIZING Z – MATRICES

In this section, we have given the basic results, lemma and the theorems of Z - matrices.

### Definition: 1.1

Suppose  $0 \neq x \in \mathbb{R}^n$  and  $y \in \mathbb{R}^n$ . Let P be the permutation matrix chosen so that

$$P_x = \begin{bmatrix} X_1 \\ X_2 \\ X_3 \end{bmatrix} \text{ In which } X_1 > 0, X_2 > 0$$

and  $X_3 = 0$  (entry - wise) and suppose that

$$P_y = \begin{bmatrix} Y_1 \\ Y_2 \\ Y_3 \end{bmatrix}$$

is partitioned conformally with  $x$ . Except for  $X_1$  and  $X_2$  any one or two of  $X_1, X_2$  and  $X_3$  may be empty.

## Consider the following properties :

(P<sub>1</sub>) If  $X_1$  is empty and  $X_3$  is not, then  $Y_3 \geq 0$  and if  $X_2$  is empty and  $X_3$  is not, then  $Y_3 \leq 0$

$$(P_2) X_1 \circ Y_1 \not\leq 0 \text{ and } X_2 \circ Y_2 \not\leq 0$$

$$(P_3) X_1 \circ Y_1 \not\geq 0 \text{ and } X_2 \circ Y_2 \not\geq 0$$

## LEMMA : 1.2

Let  $A \in M_n(\mathbb{R})$ . Then  $A \in Z$  if and only if for each  $0 \neq x \in \mathbb{R}^n$ .

$x$  and  $Ax$  satisfy (P<sub>1</sub>).

## PROOF :

Let  $A \in M_n(\mathbb{R})$ .

If  $n = 1$ , the result is clear.

Assume hence forth then  $n \geq 2$ .

In order to prove necessity, assume that  $A \in Z$  and

$$0 \neq x = \begin{bmatrix} X_1 \\ X_2 \\ X_3 \end{bmatrix} \in \mathbb{R}^n.$$

in which  $X_1 > 0, X_2 < 0$  and  $X_3 = 0$ . If  $X_1$  is empty and  $X_3$  is not, then, partitioning  $y$  and  $A$  conformally with  $x$ , we have

$$Y = \begin{bmatrix} Y_2 \\ Y_3 \end{bmatrix} = \begin{bmatrix} A_{22} & A_{23} \\ A_{32} & A_{33} \end{bmatrix} \begin{bmatrix} X_2 \\ X_3 \end{bmatrix} = AX$$

[ since  $x \neq 0, X_2$  is non empty ].

Thus,

$$Y_3 = A_{32}, X_2 \geq 0.$$

Similarly,

if  $X_2$  is empty and  $X_3$  is not, it follows that  $Y_3 \leq 0$ .

Thus ,  
x and Ax satisfy by ( P<sub>1</sub> ) .  
Conversely ,

Assume the contrary , say a<sub>ij</sub> > 0 some i ≠ j .  
If x = - e<sub>i</sub> , then X<sub>1</sub> is empty and X<sub>3</sub> is not .  
But Y<sub>3</sub> ≠ 0 , which contradicts ( P<sub>1</sub> ) .  
Hence the lemma .

**THEOREM : 1.3**

Let A ∈ M<sub>n</sub>( R ) . Then A ∈ K<sub>0</sub> if and only if for each 0 < x ∈ R<sup>n</sup> , x and Ax are doubly closed - sign related .

**PROOF:**

Let A ∈ M<sub>n</sub>( R ) .  
Since the result is clear for n = 1 , we assume that n ≥ 2 .

Assume that for every 0 ≠ x ∈ R<sup>n</sup> . x and Ax are doubly closed - sign related .

Let 0 ≠ x ∈ R<sup>n</sup> .  
Then x and Ax satisfy ( P<sub>1</sub> ) and ( P<sub>3</sub> ) .  
Hence , applying the lemma ( 2.2 ) , A ∈ Z . Further , since x ≠ 0 , ( P<sub>3</sub> ) implies that there is a subscript i such that x<sub>i</sub> ≠ 0 and x<sub>i</sub> y<sub>i</sub> ≥ 0 .  
This , in turn , implies that A is an M - matrix .  
Conversely ,

Suppose that A is an M - matrix , 0 ≠ x ∈ R<sup>n</sup> and y = Ax .

Then , A ∈ Z and it follows from the lemma that ( P<sub>1</sub> ) holds . Writing x in partitioned form and partitioning y and A conformally with x , we have

$$\begin{bmatrix} Y_1 \\ Y_2 \\ Y_3 \end{bmatrix} = \begin{bmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ A_{31} & A_{32} & A_{33} \end{bmatrix} \begin{bmatrix} X_1 \\ X_2 \\ X_3 \end{bmatrix}$$

in which X<sub>1</sub> > 0 , X<sub>2</sub> < 0 and X<sub>3</sub> = 0 . Thus assuming X<sub>1</sub> is non empty , we have Y<sub>1</sub> = A<sub>11</sub> X<sub>1</sub> + A<sub>12</sub> X<sub>2</sub> or A<sub>11</sub> X<sub>1</sub> = Y<sub>1</sub> - A<sub>12</sub> X<sub>2</sub> .

Now if Y<sub>1</sub> < 0 , it follows that A<sub>11</sub> X<sub>1</sub> < 0 .

Thus , there is ε > 0 such that ( A<sub>11</sub> + ε I ) X<sub>1</sub> < 0 .

But this contradicts the fact that A<sub>11</sub> + ε I is a non singular M - matrix and hence a P - matrix .

Thus , Y<sub>1</sub> = 0 . So ( P<sub>3</sub> ) holds .  
Hence the theorem .

**THEOREM : 1.4**

Let A ∈ M<sub>n</sub>( R ) . Then A ∈ N<sub>0</sub> if and only if

- ( i ) for each 0 < x ∈ R<sup>n-1</sup> and every i ∈ N , x and Ax are doubly closed - sign related and
- ( ii ) there is a vector 0 < x̂ ∈ R<sup>n</sup> such that A x̂ .

**PROOF :**

Let A ∈ M<sub>n</sub>( R ) . if A ∈ N<sub>0</sub> , then each proper submatrix is an H - matrix and it follows from theorem 2.3 that ( i ) holds .

Now A = t I - B in which B ≥ 0 is irreducible and ρ<sub>n-1</sub>( B ) ≤ t ≤ ρ( B ) .

There is a positive vector x̂ ∈ R<sup>n</sup> such that B x̂ = ρ<sup>(B)</sup> x̂ .

Thus , A x̂ = ( t I - ρ( B ) ) x̂ < 0 .

Conversely ,

Suppose that A satisfies ( i ) and ( ii ) , say A x̂ = y < 0 . Then there is ε > 0 such that

$$( A + ε I ) x̂ = Z < 0 .$$

Since ( i ) holds , A ∈ Z and it follows from theorem ( 2.3 ) that principal submatrices of order n - 1 are M - matrices .

Thus , A is either an M - matrix or an N<sub>0</sub> matrix .  
If A is an M - matrix , then A + ε I is non - singular M - matrix and hence ( A + ε I )<sup>-1</sup> ≥ 0 .  
Hence , x̂ = ( A + ε I )<sup>-1</sup> Z < 0 , a contradiction .  
Thus , A is an N<sub>0</sub> matrix .  
Hence the proof .

**THEOREM : 1.5**

Let A ∈ M<sub>n</sub>( R ) in which n ≥ 3 . For k = 1 , 2 , ... , n - 2 , A ∈ L<sub>k</sub> if and only if

- ( i ) for each 0 ≠ x ∈ R<sup>k</sup> and every α ⊆ N with | α | = k , x and A [ α ] x are doubly closed sign - related and
- ( ii ) there is β ⊆ N with | β | = k + 1 and a vector 0 < x̂ ∈ R<sup>k+1</sup> such that A [ β ] x̂ < 0 .

**PROOF :**

Let A ∈ M<sub>n</sub>( R ) and k ∈ { 1 , 2 , ... , n - 2 } .

If A ∈ L<sub>k</sub> , then each proper principal submatrix of order k is an M - matrix and it follows from theorem ( 2.3 ) that ( i ) holds .

Further there is β ⊆ N with | β | = k + 1 such that A [ β ] is an N<sub>0</sub> - matrix , say A [ β ] = t I - B = ρ( B ) .

Let x̂ be the Perron vector associated with ρ( B ) .

Then , A [ β ] x̂ = ( t - ρ( B ) ) x̂ < 0 .

Conversely ,

Suppose that A satisfies ( i ) and ( ii ) for some k ∈ { 1 , 2 , ... , n - 2 } say A [ β ] x̂ = Y < 0 in which is β ⊆ N with | β | = k + 1 .

Since (i) holds and  $A \in Z$  and it follows from theorem (2.3) that all principal submatrices of order  $k$  or less are  $M$ -matrices.

Then it follows from theorem (2.4) that  $A[\beta]$  is an  $N_0$ -matrix.

Thus,  $A \in L_k$ .  
 Hence the proof.

**THEOREM : 1.6**

Let  $A \in M_n(\mathbb{R})$ . Then Let  $A \in L_0$  if and only if

(i) for every  $0 \neq x \in \mathbb{R}^n$ ,  $x$  and  $Ax$  satisfy  $(P_1)$  and

(ii) for every  $k \in \mathbb{N}$ , there is  $0 \neq x \in \mathbb{R}^n$  and  $\alpha \subseteq \mathbb{N}$  with  $|\alpha| = k$  such that  $x \circ A[\alpha]x \leq 0$ .

**PROOF :**

Let  $A \in M_n(\mathbb{R})$  and  $K \in \mathbb{N}$ .

If  $A \in L_0$  then  $A \in Z$  and (i) follows from the lemma.

Further  $A$  has at least one negative diagonal entry, say  $a_{ij}$ .

Then, for each  $\alpha \subseteq \mathbb{N}$  with  $|\alpha| = k$  and  $j \in \alpha$ ,  $A[\alpha]e_j \leq 0$ , where  $e_j$  denote the  $j^{\text{th}}$  standard basis vector.

Thus,  $e_j \circ A[\alpha]e_j \leq 0$ , which establishes necessity.

Conversely,

Suppose (i) and (ii) holds.

Since (ii) holds,  $A \in Z$  and in light of the theorems (2.3 – 2.5).

(ii) implies that  $A \notin L_k$  for  $k \in \mathbb{N}$ .

Thus,  $A \in L_0$ , which completes the proof.  
 Hence the theorem.

**Z – MATRICES AND ITS INVERSE**

**2.1 Z – MATRICES**

In this chapter we have 2 sections. In this section we have the  $Z$ -matrices and inverse  $Z$ -matrices.

**DEFINITION : 2.1.1**

Let  $L_s$  (for  $s = 0, \dots, n$ ) denote the class of matrices consisting of real  $n \times n$  matrices which have the form

$$A = tI - B, \text{ where } B \geq 0 \text{ and } \rho_s(B) \leq t \leq \rho_{s+1} \dots \dots \dots (3.1.1)$$

Here

$\rho_s(B) := \max \{ \rho(B) : B \text{ is an } s \times s \text{ principal submatrix of } B \}$  and we get

$\rho_0(B) := -\infty$  and  $\rho_{n+1}(B) := \infty$ .

**REMARK : 2.1.2**

If one considers matrices of different dimensions, one should introduce another index which gives the dimension of the matrices. Hence one should use  $L_{s,n}$  in definition (3.1.1). Then the two classes  $L_{s,n}$  and  $L_{t,m}$  consist of matrices of the same type. (eg.  $M$ -matrices,  $N_0$ -matrices) if and only if  $n - s = m - t$ .

**THEOREM : 2.1.3**

Let  $A \in \mathbb{R}^{n \times n}$  be a nonsingular matrix, and let  $\lambda$  be a real eigen value of  $A$  with  $\lambda \neq \rho(A)$ . Then

$$\lambda \leq \rho_{[n/2]}(A) \dots \dots \dots (3.1.2)$$

Since  $Z$ -matrices are closely related to non negative matrices, we now obtain.

**THEOREM : 2.1.4**

Let  $A \in L_s$ . Then

- (i)  $\det A \geq 0$  if  $s = n$ ,
- (ii)  $\det A \leq 0$  if  $[n/2] \leq s < n$ .

**PROOF :**

It is well known that (i) holds.

Let  $A \in L_s$  with  $A = tI - B$ ,  $B \geq 0$  and a fixed  $t \in \mathbb{R}$ .

Now consider the characteristic polynomial of  $B$ ,

$$\chi(z) = \det(zI - B).$$

The real zeros of  $\chi(z)$  indicate the changes of the sign of the determinant of  $Z$ -matrices corresponding to the matrix  $B$ . But the zeros of  $\chi(z)$  are the eigen values of  $B$ .

Hence, with theorem 3.1.3 (ii) follows.

Hence the theorem.

**EXAMPLE : 2.1.5**

Let  $J_k$  denote the  $k \times k$  matrix of all ones. First assume that  $n$  is even. Let  $r := n/2$ . Then let  $A_{11} := \alpha I_r - J_r$  and  $A_{22} := \beta I_{n-r} - J_{n-r}$ .

If  $s \leq \alpha$ ,  $\beta < s + 1$ ; then  $\alpha I_r - J_r$  and  $\beta I_{n-r} - J_{n-r}$  are in  $L_s$ .

Now, if  $s < n/2$ , then  $\det A_{11} < 0$  and  $\det A_{22} < 0$ .

However,  $A = A_{11} \oplus A_{22} \in L_s$  and  $\det A > 0$ .

Similarly, one can construct examples for an odd dimension  $n$ .

Thus, all classes of  $Z$ -matrices consisting of matrices of different dimensions, except the classes of  $M$ -matrices,  $N_0$ -matrices and  $F_0$ -matrices include matrices with different signs of their determinants.

However, if we consider the classes  $L_s$  which consist by definition of matrices of the same definition  $n$ , then  $\det A \leq 0$  if  $A \in L_s$  and  $[n/2] \leq s < n$ .

Obviously, every  $Z$ -matrix  $A$ , except an  $M$ -matrix, has at least one negative eigen value.

However, if  $A \in L_s$  with  $[n/2] \leq s < n$ , then theorem states that  $A$  has exactly one negative eigen value.

**THEOREM : 2.1.6**

Let  $A = [a_{ij}]$  be a  $Z$ -matrix. let  $\alpha(A)$  denote the smallest real eigen value of  $A$ . Let  $a = \max\{a_{ij}\}$ . Then the circle  $c(A) := \{z \in \mathbb{C} : |z - a| \leq a - \alpha(A)\}$  contains all eigen values of  $A$ .

**PROOF :**

Let  $\lambda$  be an eigen value of  $A$ .

Since  $a = \max\{a_{ij}\}$ , the matrix  $aI - A$  is nonnegative.

Hence, the modules of each eigenvalues of  $aI - A$  is less than  $\rho(aI - A)$ .

Thus,

$$|a - \lambda| \leq \rho(aI - A) = a - \alpha(A).$$

Hence the theorem.

**2.2 INVERSE Z – MATRICES**

In this section, we have definition and the theorems of Inverse  $Z$ -matrices.

**DEFINITION : 2.2.1**

A nonsingular matrix is called an inverse  $Z$ -matrix if  $C^{-1}$  is a  $Z$ -matrix. More precisely, a nonsingular matrix  $C \in R^{n \times n}$  is called inverse  $L_s$ -matrix if  $C^{-1} \in L_s$  for one  $s$  with  $S \in \{0, \dots, n\}$ .

Thus, inverse  $M$ -matrices are inverse  $L_n$ -matrices, inverse  $N_0$ -matrices are inverse  $L_{n-1}$ -matrices and inverse  $F_0$ -matrices are inverse  $L_{n-2}$ -matrices.

**THEOREM : 2.2.2**

Let  $C$  be an inverse  $Z$ -matrix partitioned as

$$C = \begin{bmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{bmatrix}$$

Where  $C_{11}$  is a non singular principal submatrix of  $C$  of arbitrary order. Then  $C / C_{11}$  is also an inverse  $Z$ -matrix.

**PROOF :**

Let  $A := C^{-1}$  be partitioned conformally with  $C$  so that

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$$

Using the explicit form of  $C^{-1}$  as in 3.2.2 we have

$$A_{22} = \left( C / C_{11} \right)^{-1}.$$

Hence,  $A_{22}$  is nonsingular. But  $A_{22}$  is a principal submatrix of a  $Z$ -matrix; therefore  $A_{22}$  itself is a  $Z$ -matrix.

Thus,  $C / C_{11} = A_{22}^{-1}$  is an  $Z$ -matrix.

Hence the theorem.

**DEFINITION : 2.2.3**

$A = [a_{ij}] \in R^{n \times n}$  is of type - D if

$$a_{ij} = \begin{cases} a_i, & i \leq j \\ a_j, & i > j \end{cases} \text{ where } a_n > a_{n-1} > \dots > a_1$$

Markham proved that the inverse of a type D -matrix  $A$ , satisfying  $a_1 > 0$  is a tridiagonal  $M$ -matrix.

**THEOREM : 2.2.4**

Suppose  $A = [a_{ij}] \in R^{n \times n}$  is a matrix of type - D with  $a_1 \neq 0$ . Let  $s$  denote the number of nonpositive parameters in the sequence  $a_n > \dots > a_1$ . Then  $A^{-1}$  is a tridiagonal  $Z$ -matrix and  $A^{-1} \in L_{s-1}$ , where  $L_{-1} := L_n$ .

**PROOF :**

Since  $a_1 \neq 0$ ,  $A$  is nonsingular. In the following we prove by induction on the dimension  $n$  that the inverse of  $A$  is a tridiagonal  $Z$ -matrix. For  $n = 1$  and  $n = 2$  this is obvious.

Now we partition  $A$  as

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$$

Such that  $A_{11} \in R^{n \times n}$  and  $A_{22} \in R^{n-r, n-r}$ ,  $1 \leq r < n$ , are non singular.

The inverse of  $A$  is given by

$$A^{-1} = \begin{bmatrix} \left( A / A_{22} \right)^{-1} & -A_{11}^{-1} A_{12} \left( A / A_{11} \right)^{-1} \\ -A_{11}^{-1} A_{21} \left( A / A_{11} \right)^{-1} & \left( A / A_{11} \right)^{-1} \end{bmatrix}$$

Proposition ( 3.2.8 ) and the inductive hypothesis yield that  $\left( A / A_{11} \right)^{-1}$  and  $\left( A / A_{22} \right)^{-1}$  are tridiagonal  $Z$ -matrices.

As seen in 3.2.4 we have  $A_{11}^{-1}A_{12} = e_r \xi_{n-r}^T$ .

Moreover, since the first diagonal entry of  $\left(\frac{A}{A_{11}}\right)$

is  $a_{r+1} - a_r > 0$ , we obtain with (3.2.3) that only the entry at position  $(r, 1)$  of

$-A_{11}^{-1}A_{12}\left(\frac{A}{A_{11}}\right)^{-1}$  is different from zero and

that this entry is negative.

Then, with the symmetry of  $A$ , we have that  $A^{-1}$  is a tridiagonal  $Z$ -matrix.

If  $s = 0$ ,  $A$  is nonnegative.

Thus,  $A^{-1}$  is an  $M$ -matrix.

If  $s \geq 1$ , it follows from (3.2.5) that  $\det A < 0$ .

Moreover, all principal minors of order greater than  $n - s$  are nonpositive.

However, the determinant of the principal matrix consisting of the rows and columns  $s + 1, \dots, n$  is positive.

But then theorem gives that  $A^{-1} \in L_{s-1}$ .  
 Hence the theorem.
